Abstract

Importance

Introduction

Scientific societies play an integral role in the formation and maintanence of scientific communities. They host conferences that provide a forum for knowledge exchange and networking, as well as opportunities for increased visibility as a researcher. Scientific societies also frequently publish the most reputable journals in their field, facilitating the peer review process to vet new research submissions. As such, societies have great power to set both professional and scientfic norms in their community by choosing what behaviors are rewarded and what types of research are accepted for publication. Publication authorship is a coveted measure of success in academia as it is a key criterium for hiring and promotion processes. Accordingly, editors and reviewers of research journals have a substantial influence over the futures of hopeful authors. While the membership of scientific societies is likely to reflective of all those who participate in the field, regardless of career track, the gatekeepers for peer review (reviewers and editors) are more reflective of the academy than the society as a whole.

Evidence has accumulated over the decades that academic research has a representation problem. While at least 50% of biology Ph.D. graduates are women, the number of women in postdoctoral positions and tenure-track positions are less than 40 and 30%, respectively @article{sheltzer_elite_2014}. Studies examining other metrics such as race and ethnicity find that less than 10% of all science and engineering doctorates were awarded to underrepresented minorities, while less than 25% of science and engineering doctorates in early career academia identify as non-white (NSF ADVANCE, 2014). Predictabily, the disparities increase alongside academic rank, a phenomenon known as hierarchical segregation @article{potvin_diversity_2018}. There have been many proposed reasons for these disparities (particularly against women) that include biases in training and hiring, the impact of children on career trajectories, a lack of support for primary caregivers, and a lack of recognition, which

culminate in reduced productivity as measured by research publications.

28 Recently, scientific societies and publishers have begun examining their own data to evaluate
29 representation of, and bias agains, women and minorities in their peer review processes. The
30 American Geological Union found that while the acceptance rate of women-authored publications
31 was greater than that for publications authored by men, women submitted fewer manuscripts than
32 men and were used as reviewers only 20% of the time (Lerback, 2017). Fox et al., have found
33 that for the journal *Functional Ecology*, the proportion of women invited to review depended on
34 the gender of the editor (Fox, 2016). Despite the disproportional representation of lead women
35 authors, several studies have concluded that there is no significant bias aginst papers authored by
36 women (C&W, 2011; Fox, 2016; Handly, 2015; Edwards, 2018). Conversely, a study of the peer
37 review process at eLife found statistically significant bias against women, particularly from review
38 groups composed of all men (Murray, 2018).

53 – eLife

However, representation and attitudes differ by scientific field and no studies to-date seem to have investigated academic publishing in the field of microbiology (Elseiver report). [Stats on ASM size/membership that make it a good study system]. In its mission statement, the American Society for Microbiology (ASM) notes that it is "an inclusive organization, engaging with and responding to the needs of its diverse constituencies." The ASM also pledges to "address all members' needs through development and assesment of programs and services" while the ASM Journals Department boasts of "quality peer review and editorial leadership." Therefore, in an effort to be transparent with ASM journal patrons and ASM members, the purpose of this study is to perform a gender-based analysis of ASM journals using submissions data aquired since 2012. In other words, what is the representation of authors, reviewers and editors during peer review at ASM journals? Does that representation reflect the field of microbiology and ASM members? And is there bias during the peer review process at ASM journals?

Results

This study uses the data from manuscripts submitted to ASM journals that had a final decision rendered between January 2012 and August 2018.

Men dominate as gatekeepers and senior authors + Editor Notes: + The proportions of men/women editors are similar for both editors and senior editors – only showed editors + There is a slow trend toward gender parity in editors + Need to add the N of each editorial group: senior editors, editors, eic – all are pooled

```
+ Who carries the editorial burden?
   + How many manuscripts are editors handling -- Women handle a higher median of papers than
   + Is it proportional to the author representation? -- in some cases, but also difficult to
   + Does it change by EiC? -- yes, CVI/JVI have EiCs that are women
```
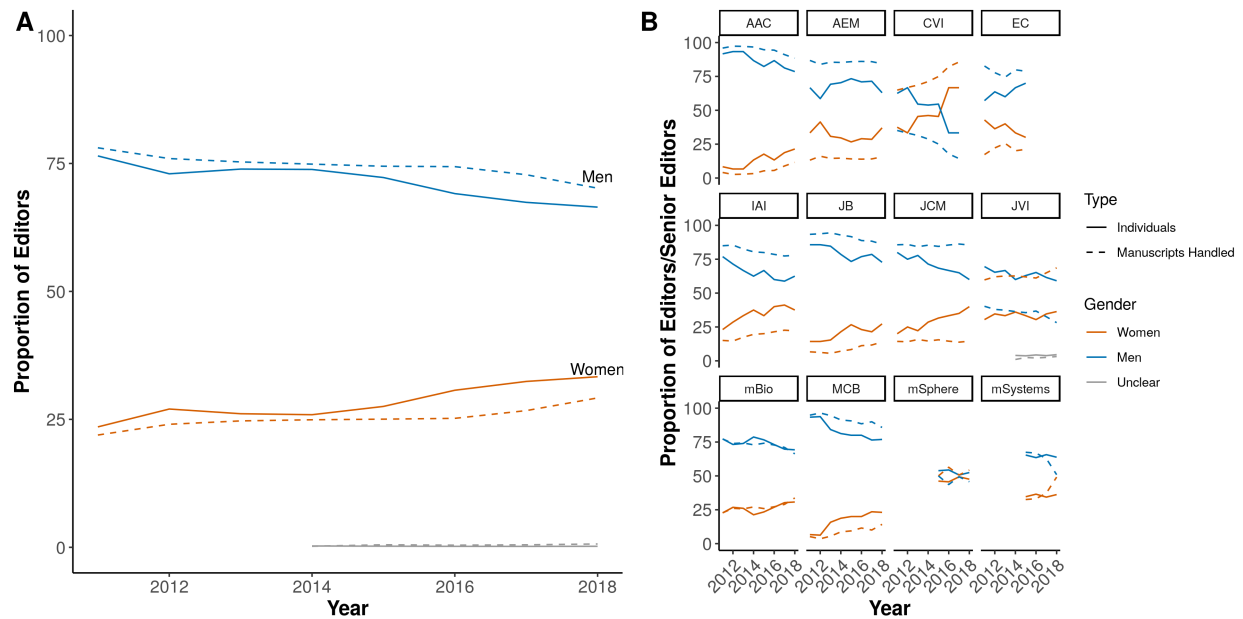

Figure 1.

- Reviewer Notes:

  - Median number of paper reviews are equivalent across genders, though men seem slightly more likely to review more papers - trends representative of journals, except for MCB where "unclear" reviewers are a greater proportion than women

  - Slight increase in the proportion of women over time (& decrease of men), more women reviewers than "unclear"

  - trends and approximate proportions are equvalent for potential reviewers and actual reviewers

  - greater # of women (unique indvidiuals) have been suggested as potential reviewers than # of women senior authors – only 1/2 have actually been reviewers

  - similar trend for min, except that the proportions of potential & accepted seem to be higher - calculate & add proportions relative to senior authors

  - different trend for "unclear" authors where senior > potential > accepted

- Who carries the burden of peer review?

  - How often are reviewers participating on multiple manuscripts? – calculate proportion

5

94   that only reviewed one paper

95   – How does representation compare from potential to actual reviewer? – seems

96   equivalent

97   – Is it proportional to the author representation? – yes

Figure 2.

100   • Notes:

101   – Proportions of men and women authors have decreased over time, while "unclear" has

102   increased – gap between men & women proportions unchanged since 2012

103   – ratio of women:men authors is 3:4

104   – First & Middle author proportions are representative

105   – Last & corresponding author proportions are representative

- Women are first authors more often than other groups – decreasing trend of men/women first authors over time (increase of unclear)
- Trends are similar across journals & genders
- proportion of women corresponding/last authors has not increased over time
- proportion of men senior authors has decreased over time – increase of unclear senior authors
- proportion of published is higher for both men & women than submitted proportions – means that proportion of unclear published is lower than submitted
- is the increase in published proportions, proportionally equivalent for men & women?
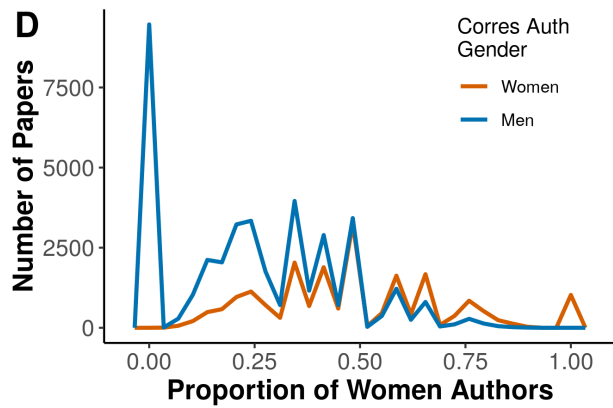

115

Figure 3.

Women are less likely to be retained through stages of the peer review system at ASM journals + How does gender representation of manuscripts compare from submitted to published? + proportion of M & W authored publications seems relatively disparate from M & W authored submissions – unknown if bias + "Publication Rate Disparity" = (M publish rate) - (W publish rate) – positive == men more likely to publish (i.e., overperform); negative == women more likely to publish + Men overperform in all authorship roles across ASM journals, most clear for corresponding authors + Break it down by journals and there is clear trend to overperformance by men in both corresponding & last authorships, some exceptions + Are women being retained through peer review at the same proportion as men/unclear? + Get actual proportions at each stage + seems as if fewer women progress through each stage than men + large proportion of potential reviewers are not senior authors (both genders) + senior authors that are women are less likely to be considered as reviewers (40 vs 50%)
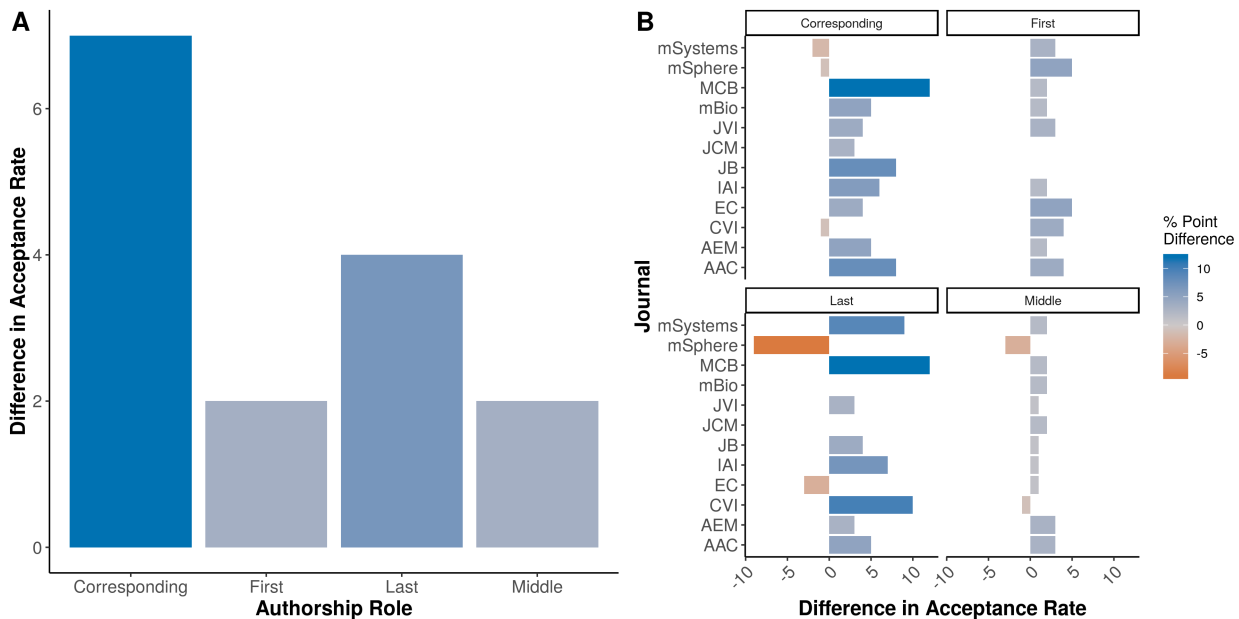

Figure 4.
Figure 5.

Papers submitted by women are rejected more frequently than those submitted by men

Figure 6.

- try to better understand the % point difference in gender-ed performance

- NOTE: to correct for the large discrepency in the participation of women at ASM journals during the is time period, all comparisions are made relative to the gender and population in question.

- direct comparision of the proportion of woman-authored papers that are rejected compared

141   to men, at each author stage

142   – middle/first author rejected at similar rates

143   – woman-authored (corres/last) rejected more frequently than men

144   – there are several journals where the overall trend is repeated and/or amplified (e.g.,

145   AAC, IAI, JB, mBio, MCB)

146   – greatest effect seen for corresponding authors, use this sub-population to further

147   examine

148   *Both men and women editors are more likely to reject papers authored by women than those*

149   *authored by men and these preferences are partially mediated by author institution*

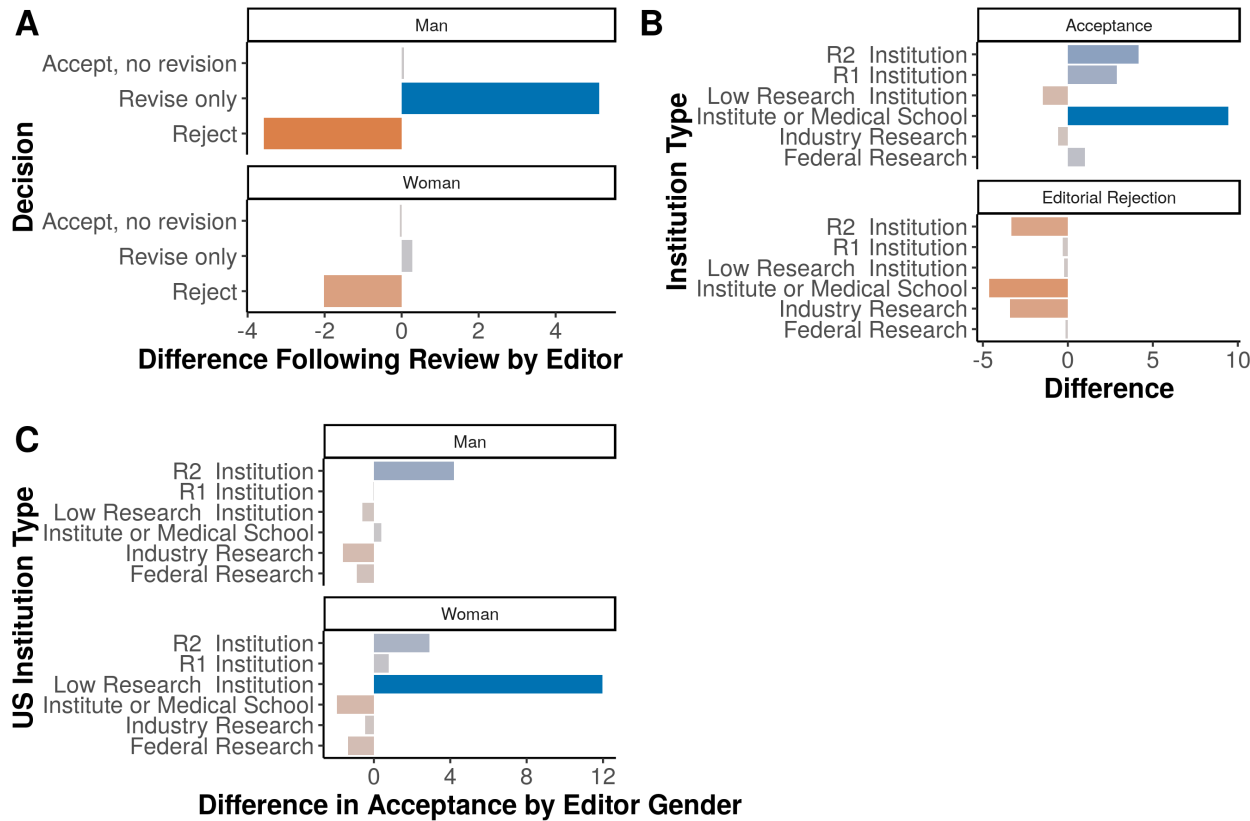

151   **Figure 7.**

152   • There are two main gatekeeping roles for manuscript decisions: editors & reviewers

153   • This section evaluates disparities made by editors during editorial rejections, and decisions

12

154 following peer review.

155 • Women recieve more editorial rejections than men, proportionally (editorial_rejections.R)

156 • may be complications due to geographic bias (eLife paper), restrict to papers submitted in
157   US & examine institution type

158 • slight disparity in editorial rejection & acceptance rates according to institution type
159   (rej_by_inst_type.R)

160   – greatest difference (4%) occurs for institute/medical schools

161   – trend holds for most journals and is >20% diff at JCM (R2s), mBio (Federal), MCB (low
162   research), AEM (industry research) (Supplementary_A)

163   – men from institutes/medical schools outperform women >7% for acceptance across all
164   journals

165   –   20% in favor of men at: EC (fed researh), mSphere & JVI (Low research), AEM
166   & MCB (industry research), JCM/JB/JCM (R2 institution) (Supplementary_B)

167 • both men & women editors are more likely to reject women (editor_gender_analysis.R)

168   – men editors are more likely to make revise only & accept decisions for men

169   – women editors highly favor men from medical schools, slightly favor men from R2 &
170   industry – what is the n?

171   – men editors favor men from R1, R2 and medical schools, slightly favor women from low
172   & industry research – what is the n?

173 *Both men and women reviewers more frequently suggest rejection for papers authored by women*
Figure 8.

- rev_score_analysis.R

  – reviewers are more likely to suggest rejections for women as compared to men. No difference in revise decisions (A)

  – men at R1, low research, medical schools & fed research are favored by reviewers over women (B)

- reviewer_gender_analysis.R

  – both female & male reviewers are more likely to recommend rejection for women. (C)

  – Male reviewers are more likely to accept papers from men (C)

  – women reviewers are more likely to recommend acceptance for women from low

14

185   research & federal institutions (D)

186   – women reviewers are more likely to recommend acceptance for men from R1 & industry

187   instutitions (C)

188   – men are more likely to recommend acceptance for women from R2 institutions & favor

189   men from R1 & medical institutes (D)

*Factors affecting competency*

190

Figure 9.

192

193   • In addition to rejectance/acceptance rates, other disparate outcomes may occur during the

194   peer review process

195   • Time in Peer Reivew (time_to_publication.R)

196   – Papers published by women take slightly longer (from submission to ready for

15

publication) than men at some journals (mSphere, mBio, mSystems, CVI, JB, JCM, AEM) despite spending similar amounts of time at ASM journals (A, B)

– but do not require a greater number of revisions to be accepted than men (Supplementary_C)

– Papers rejected following review that were submitted by women do not generally take longer (in days) to be rejected (except at mSystems) or have more revisions (Supplementary_D & _E)

– Decisions are returned to men & women similarly (time_at_journ.R)

• Peer review is not a linear process, it is cyclical and builds upon its self, may also be disparities in impact (impact_analysis.R)

– Women tend to receive lower cites per month published than men

– HTML/PDF/Abstract views are equivalent

– women are more likely to be published in lower JIF journals

– No disparity in gendered sumissions to high (mBio) vs lower (mSphere) journals (bias_by_jif.R)

Discussion

• Summarize results

– Gender

* Women/men/unclear are X percent of authors, reviewers, editors

* Women/men/unclear are more likely to be repeat authors/submitters

* M are more likely than W to be suggested as reviewers and are/are not used as reviewers at the same proportion

* M/F editors are more likely to handle multiple manuscripts – depends on journal

* Women are not retained to the same extent as men/unclear

* These observations do/do not correlate with gender of EiC

* gap between men & women peformance, rejection rates

16

- - - * women more likely to be editorially rejected or given rejection after review
    - – Compare to global and ASM membership stats
    - – Globally - microbiology researchers are 60:40, M:F - Elsevier
    - – ASM membership -

- fit into context of field –
    - – few papers have found disparties between rejection rates of men & women
    - – first paper (to our knowledge) to collectly examine this issue on 10+ journals using submissions data
    - – literature to connect institution type findings
        - * compentency?
        - * access to resources
        - * "family friendly"/less committed institutions
        - * other sterotypes

- study limitations
    - – doesn't include reviewer comments
    - – limited journal dataset, difficult to know how other microbiology-publishing journals affect submissions to ASM journals
    - – many ASM journals have a narrow focus, & broad scope journals are relatively new – limits conclusions b/c of journal selection

- Discuss the impact of under representation in publication
    - – "It [reviewing] provides positive feedback that a scholar is respected and participating in their field and fosters self-confidence, all of which lead to increased retention of women in geoscience" Lerback & Hanson, 2017
    - – Less diversity may reduce the diversity of perspectives & approaches valued & represented. - Fox et al, 2016
    - – Thus authors conclude it is an issue of female "visibility" versus "availability". Suggestion that being selected as a reviewer increases visibility, which has a direct & significant impact on salary. , under-rep of W in Sci b/c of positions w. fewer resources.

17

"Participating in the peer-review process is an important way that early-career researchers can feel more involved with, and contribute to, the scientific community" - Buckley et al, 2014

- Must be balanced w. the increased burden for department service

• Discuss literature on diversity and innovation - incentive to increase representation - well-documented that orgs w. more diverse & equitable representation are both more inclusive & supportive as well as more productive & innovative - Potvin, 2018

• Suggestions to improve representation

- Apply the additional suggestions from the Scientific Society health checklist to society journals:

  1. Include a visible mission/vision statement or other commitment to equality & diversity that includes a non-discrimination clause regarding editors & EiCs
  2. Collect additional data (e.g., race/ethnicity, sexual/gender minorities) & present numbers publicly to maintain accountability
  3. Have a specific protocol for the reporting of & responding to discrimination & harassment
  4. Be explicit about support for women (& other minority groups). + Formally (e.g., providing waivers, reduced copyediting services, reword to gender/location-neutral) + Informally (e.g., rewarding inclusive behavior by candidates, encouraging women to take up leadership positions, have gender-neutral, non-exclusive, family-friendly social activities)

- Representational vs aspirational?

  * Largest & less visible workload (reviewing) should be representational + When choosing reviewers it may be better for editors to rely more on manuscript reference lists & data base searches than on personal knowledge - Fox et al, 2016 + Suggest more women as reviewers + Improve backend/interactivity of peer review selection
  * Higher visibility workload (editor, EiC) should be aspirational, recruit more women

• fit into context of field –

279 – few papers have found disparties between rejection rates of men & women

280 – first paper (to our knowledge) to collectly examine this issue on 10+ journals using

281 submissions data

282 – literature to connect institution type findings

283 * compentency?

284 * access to resources

285 * "family friendly"/less committed institutions

286 * other sterotypes

287 • study limitations

288 – doesn't include reviewer comments

289 – limited journal dataset, difficult to know how other microbiology-publishing journals

290 affect submissions to ASM journals

291 – many ASM journals have a narrow focus, & broad scope journals are relatively new –

292 limits conclusions b/c of journal selection

293 • addressing bias

294 – implicit bias training is insufficient

295 – double-blinded peer review also imperfect

296 * common practice in social sciences

297 * can then be unblinded following decision

298 – focus on the system & structure rather than the individual - e.g., journal scope, funding

299 – increase diversity of gatekeepers

300 * increase inclusivity & goodwill/author buy-in

301 * use "Diversify" resources

302 * women/urm at "fringes" of fields, less likely to be viewed as "competent"

303 **Data and Methods**

304 *Data*

All manuscripts handled by ASM journals (e.g., *mBio*, *Journal of Virology*) that recieved an editorial decision between January 1st, 2012 and August 31st, 2018 were supplied as XML files by ASM's publishing platform, eJP. Data were extracted from the XML documents provided using R statistical software (version 3.4.4) and the `XML` package (R citation). Data manipulation was handled using the `tidyverse`, `lubridate`, and `xml2` packages for R. Variables of interest included: the manuscript number assigned to each submission, manuscript type (e.g., full length research, erratum, editorial), category (e.g., microbial ecology), related (previously submitted) manuscripts, versions submitted, dates (e.g., submission, decision), author data (e.g., first, last, and corresponding authorships, total number of authors), reviewer data (e.g., reviewer score, recommendation, editor decision), and person data (names, institutions, country) of the editors, authors, and reviewers.

Data analysis and presentation

For this analysis, only original, research-based manuscripts were included, e.g., long- and short-form research articles, New-Data Letters, Observations, Opinion/Hypothesis articles, and Fast-Track Communications.

It is common practice at ASM journals for manuscripts whose reviewers recommend extensive experimental revisions be given a decision of "reject with resubmission encouraged". If resubmitted, the authors are asked to note the previous (related) manuscript and the resubmission is assigned a new manuscript number. Multiple related manuscripts were tracked together by generating a unique grouped manuscript number based on the recorded related manuscript numbers. This grouped manuscript number served multiple purposes including: tracking a single manuscript through multiple rejections or transfers between ASM journals and to avoid duplicate counts of the same authors for the same manuscript.

Data were visualized using the `ggplot`, `scales`, `RColorBrewer`, and `ggalluvial` packages for R.

Gender prediction and assignment

The gender assignment API genderize.io was used to predict an indivdual's gender based on their given names, and country where possible. The genderize.io platform uses data gathered from

20

social media to predict gender based on given names with the option to include an associated language or country to enhance the odds of succesful prediction. Since all manuscripts are submitted in English, precluding language association for names with special characters, names were standarized to ASCII coding (e.g., "José" to "Jose"). We next matched each individuals country against the list of X country names accepted by genderize.io. Using the `GenderGuesser` package for R, all unique given names associated with an accepted country were submitted to the genderize.io API and any names returned without a predictive assignment of either male or female were resubmitted without an associated country. All predictive assignments of either male or female are returned with a probability match of 0.50 or greater. The predicted genders of all given names (with and without an associated country) whose probabilities were greater or equal to our arbitrary success cut off of 0.65 were used to assign predicted gender to the individuals in our dataset. Predicted genders were assigned to individuals in the following order: first names and country, first names, middle names and country, middle names (Supplemental Figure 1). The presenting gender (man/woman) of editors and senior editors in our dataset was hand validated using Google where possible.

We recognize that biological sex (male/female) is not always equivalent to the gender that an individual presents as (man/woman), which is also distinct from the gender(s) that an individual may self-identify as. For the purposes of this manuscript, we choose to focus on the presenting gender (man/woman/unclear) based on their first names and/or appearance (for editors). In the interest of transparency, we include those individuals whose names don't allow a high degree of confidence for gender assignment in the "unclear" category of our analysis.

Validation of gender prediction

We first validated the algorithm using a set of 3265 names whose gender had been hand-coded based on appearance and were generously provided to us by ___ (preprint cite). The names were supplied to the genderize algorithm both with and without the accompanying country data. The data returned include the name, predicted gender (male, female, na), the probability of correct gender assignment (ranging from 0.5 to 1.0), and the number of instances the name and gender were associated together (1 or greater). The genderize algorithm returned gender predictions for

2899 when first names were given and 2167 when country data was also supplied (732 names were associated with countries unsupported by genderize).

Senstivity and specificity, are measurements of the algorithm's tendency to return correct answers instead of false positives (e.g., a man incorrectly gendered as a woman) or false negatives (e.g., a woman incorrectly gendered as a man). The closer these values are to 1, the smaller the chance that the algorithm will return the correllating false reponse. Accuracy is a composite measure of the algorithm's ability to differentiate the genders correctly. These measurements were calculated from the datasets (with and without country data supplied) at three different probability threshold cutoffs: the default genderize (0.5), a probability threshold of 0.85 (0.85), and a modified probability of 0.85, which factors in the number of instances returned (pmod0.85)(citations).

At the 0.5 threshold, the dataset returned a sensitivity of 0.8943 and specificity of 0.9339 for an accuracy of 0.911, compared to a marginally higher accuracy of 0.9146 for the dataset where country data were included (Supplemental Table 1). Generally speaking, the accuracy increases as the threshold increases along with slight tradeoffs between sensitivity and specificity. For the purposes of our analysis, we opted to use the pmod0.85 threshold moving forward (Supplemental Table 1, in bold).

To understand the extent of geographic bias in our gender assignment against regions and languages with genderless naming conventions, or that lack social media for incorporation into the genderize algorithm, we compared the number of names predicted without associated country data to when country data was also supplied. In our test dataset, the top five countries associated with names were United States, Germany, United Kingdom, France, and China and the countries with the highest proportion of un-predicted genders when country data were supplied are Cambodia, Iceland, Indonesia, Ireland, and Mexico, where the maximum number of names supplied ranged from 1 to 15. To determine the impact of each country towards the overall percentage of names whose genders were not predicted (27.14%), we found the difference between the percent of names unpredicted for each country and the overall percentage, multiplied by the proportion of observations from that country to the total observations and finally divided by the overall percentage of unpredicted names (Supplemental Figure 2). The top five countries with

388 the greatest impact on unpredicted names, and thus the countries recieving the most negative

389 bias from genderize were Canada, China, Ireland, Belgium, and Sweden (Supplemental Figure

390 3). These data suggest that there is likely some bias against countries with gender-neutral naming

391 conventions (China), and indicates the stringency with which the algorithm applies gender to

392 names that are accompanied by country data. For instance, strongly gendered names such as

393 Peter and Pedro were not assigned gender when associated with Canada.

394 We next applied the genderize algorithm at the pmod0.85 threshold to our journals dataset and

395 tested its validity on a small portion. All first names collected from our dataset were submitted to

396 genderize both with and without country data. Only those predictions whose pmod were equvalent

397 or greater than 0.85 were carried to the next step. The predicted genders were assigned to

398 individuals in the following order: first names and country, first names, middle names and country,

399 middle names. Given the relatively small number of editors and senior editors in our dataset, the

400 presenting gender (man/woman) of editors and senior editors in our dataset was hand-validated

401 using Google where possible. Of the 1072 editor names, 938 were predicted by genderize for an

402 accuracy of 0.9989339, thus increasing our confidence in the gender predictions where made.

403 In our full dataset, the five countries with the most individuals were United States, China, Japan,

404 France, and Germany and the countries with the highest proportion of un-predicted genders were

405 Burundi, Chad, Kingman Reef, Korea (North), Democratic People's Republic of, and Maldives,

406 where the maximum number of names supplied ranged from 1 to 4. Proportionally, fewer names

407 in our full dataset were assigned gender than in our validation dataset (40.01% unpredicted versus

408 27.14% unpredicted, respectively). Since adjusting the workflow to predict the gender of names

409 both with and without country data, the countries recieving the most negative bias from genderize

410 were China, Japan, Korea, Republic of, India, Taiwan, Province of China (Supplemental Figure 4).

411 These data indicate what we previously predicted, that the genderize algorithm has bias against

412 countries with gender-neutral naming conventions.
